Introduction to Computer Science: Programming Methodology

Lecture 9 Recursion, Stack and Queue

Tongxin Li
School of Data Science

Linear Recursion

- If a recursive function is designed so that each invocation of the body makes **at most one** new recursive call, this is known as **linear recursion**
- Finding the smallest number and binary search are both linear recursive algorithms

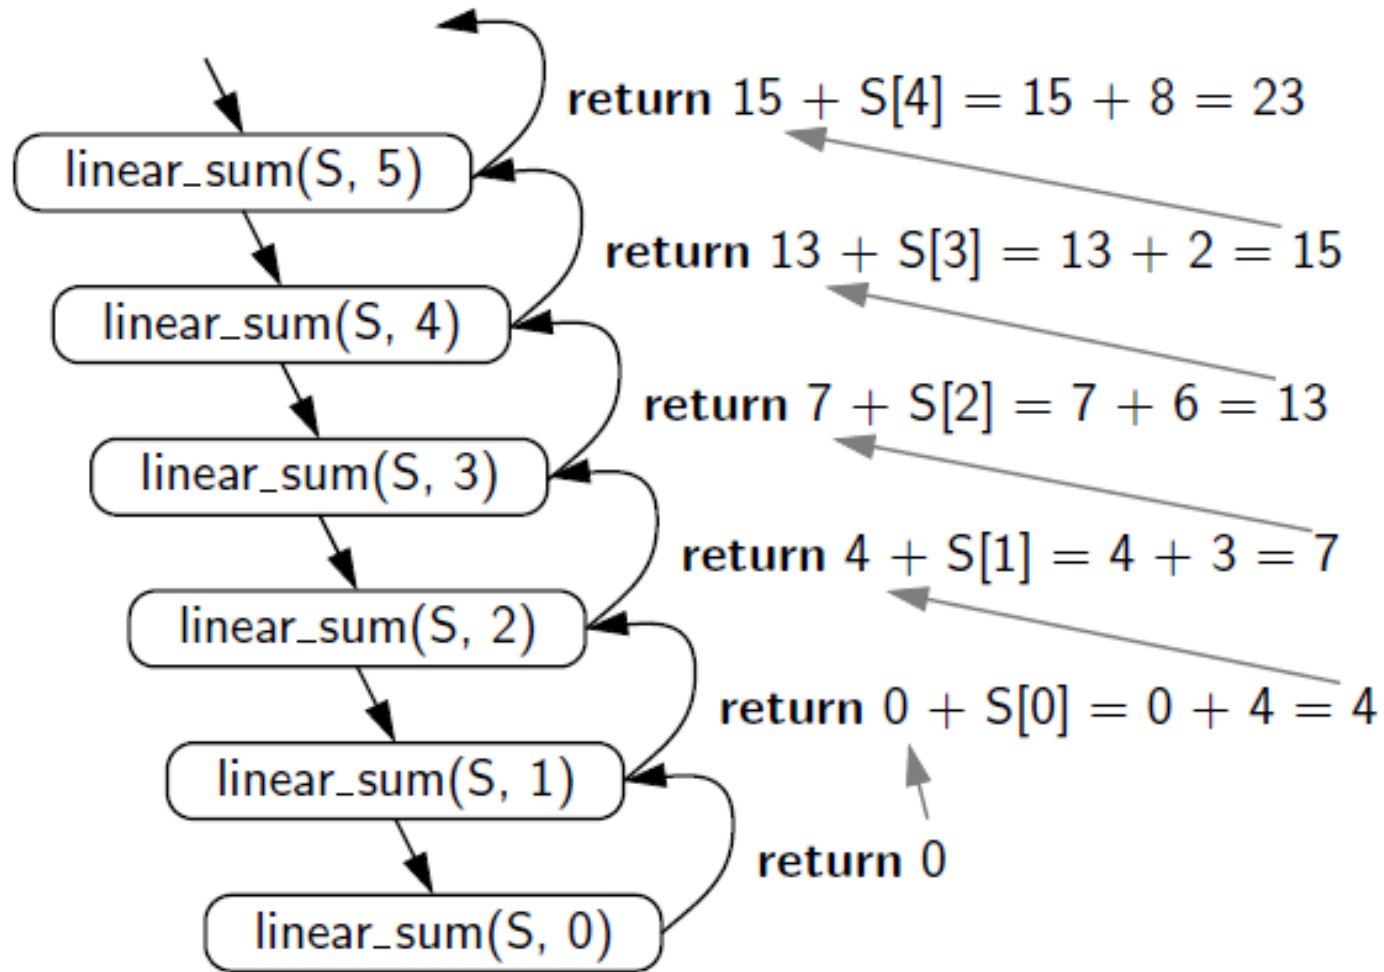

Practice: Sum of a list

- Given a list of numbers, write a program to calculate the sum of this list using recursion

Solution:

```
def linearSum(L, n):  
    if n==0:  
        return 0  
    else:  
        return linearSum(L, n-1)+L[n-1]  
  
def main():  
    L = [1, 2, 3, 4, 5, 9, 100, 46, 7]  
    print('The sum is:', linearSum(L, len(L)))
```

The recursive trace for recursive sum

Practice: Power function

- Write a program to calculate the power function $f(x, n) = x^n$ using Recursion. The time complexity of the program should be $O(\log n)$

A better recursive definition of power function

$$power(x, n) = \begin{cases} 1 & \text{if } n = 0 \\ x \cdot (power(x, \lfloor \frac{n}{2} \rfloor))^2 & \text{if } n > 0 \text{ is odd} \\ (power(x, \lfloor \frac{n}{2} \rfloor))^2 & \text{if } n > 0 \text{ is even} \end{cases}$$

Solution:

```
def myPower(x, n):  
    if n==0:  
        return 1  
    else:  
        partial = myPower(x, n//2)  
        result = partial * partial  
        if n%2==1:  
            result = result * x  
        return result
```

Multiple recursion

- When a function makes **two or more** recursive calls, we say that it uses **multiple recursion**
- Drawing the English ruler is a multiple recursion program

Practice: Binary sum

- Write a function `binarySum()` to calculate the sum of a list of numbers. Inside `binarySum()` two recursive calls should be made

Solution:

```
def binarySum(L, start, stop):  
    if start >= stop:  
        return 0  
    elif start == stop - 1:  
        return L[start]  
    else:  
        mid = (start + stop) // 2  
        return binarySum(L, start, mid) + binarySum(L, mid, stop)  
  
def main():  
    L = [1, 2, 3, 4, 5, 6, 7]  
    print(binarySum(L, 0, len(L)))
```

Exercise

- Print reversed numbers of an array using Recursion
 - [1,2,3] - > 3, 2, 1

Exercise

- Merge sort
 - Sort an array using Recursion
 - Worst-case time complexity?

Exercise

- Merge sort
 - Sort an array using Recursion
 - Worst-case time complexity? $O(n \cdot \log n)$
 - Space complexity?

Exercise

- Merge sort
 - Sort an array using Recursion
 - Worst-case time complexity? $O(n \cdot \log n)$
 - Space complexity? $O(n)$!

```
def merge_sort(arr):
    # Base case: arrays with less than 2 elements are already "sorted"
    if len(arr) <= 1:
        return arr

    # Divide the array into two halves
    mid = len(arr) // 2
    left_half = arr[:mid]
    right_half = arr[mid:]

    # Recursively sort both halves
    sorted_left = merge_sort(left_half)
    sorted_right = merge_sort(right_half)

    # Merge the sorted halves
    return merge(sorted_left, sorted_right)

def merge(left, right):
    merged = []
    i = j = 0

    # Merge the two arrays while comparing their elements
    while i < len(left) and j < len(right):
        if left[i] <= right[j]:
            merged.append(left[i])
            i += 1
        else:
            merged.append(right[j])
            j += 1

    # Append any remaining elements from the left or right subarray
    merged.extend(left[i:])
    merged.extend(right[j:])

    return merged
```

Stack

- A **stack** is a collection of objects that are inserted and removed according to the **last-in, first-out (LIFO)** principle
- A user may **insert** objects into a stack **at any time**, but may only access or remove the most recently inserted object that remains (**at the so-called “top” of the stack**)

Example: Web Browser

- Internet Web browsers store the addresses of recently visited sites in a stack. Each time a user visits a new site, that site's address is "pushed" onto the stack of addresses. The browser then allows the user to "pop" back to previously visited sites using the "back" button.

Example: Text editor

- Text editors usually provide an “undo” mechanism that cancels recent editing operations and reverts to former states of a document. This undo operation can be accomplished by keeping text changes in a stack.

The stack class

- Generally, a stack may contain the following methods:

S.push(e): Add element *e* to the top of stack *S*.

S.pop(): Remove and return the top element from the stack *S*;
an error occurs if the stack is empty.

S.top(): Return a reference to the top element of stack *S*, without
removing it; an error occurs if the stack is empty.

S.is_empty(): Return True if stack *S* does not contain any elements.

len(S): Return the number of elements in stack *S*; in Python, we
implement this with the special method `__len__`.

The Code of Stack Class

```
class ListStack:
```

```
    def __init__(self):  
        self.__data = list()
```

```
    def __len__(self):  
        return len(self.__data)
```

```
    def is_empty(self):  
        return len(self.__data) == 0
```

```
    def push(self, e):  
        self.__data.append(e)
```

```
    def top(self):  
        if self.is_empty():  
            print('The stack is empty.')        else:  
            return self.__data[self.__len__()-1]
```

```
    def pop(self):  
        if self.is_empty():  
            print('The stack is empty.')        else:  
            return self.__data.pop()
```

The code to use stack class

```
def main():  
    s = ListStack()  
    print('The stack is empty? ', s.is_empty())  
    s.push(100)  
    s.push(200)  
    s.push(300)  
    print(s.top())  
    print(s.pop())  
    print(s.top())
```

Practice: Reverse a list using stack

- Write a program to reverse the order of a list of numbers using the stack class

Solution:

```
from stack import ListStack

def reverse_data(oldList):
    s = ListStack()
    newList = list()

    for i in oldList:
        s.push(i)

    while (not s.is_empty()):
        mid = s.pop()
        newList.append(mid)

    return newList

def main():
    oldList = [1, 2, 3, 4, 5]
    newList = reverse_data(oldList)
    print(newList)
```

Practice: Brackets match checking

- In correct arithmetic expressions, the opening brackets must match the corresponding closing brackets. Write a program to check whether all the opening brackets have matched closing brackets.

Brackets match checking

- In programming languages, there are many instances when symbols must be balanced
 - E.g., { }, [], ()
- Stack can be used for checking if the symbols are balanced
 - Balanced
 - (){}[]
 - ({}[])
 - ({}[])
 - Unbalanced
 - []
 - (){}([])
 - (){}[]

Balanced symbol checking

- **Observation**

- If the next symbol is the opening symbol, e.g., (, [, {
 - Wait to see it matches closing symbols
- If the next symbol is the closing symbol, e.g.,),], }
 - It needs to match previous symbols
 - E.g., if the next symbol is “)”, for a balanced expression, there must exist some “(“ in the prefix to match it

Balanced symbol checking algorithm

- **Step 1:** Create an empty stack
- **Step 2:** Read the symbols from the input text
 - If the symbol is an opening symbol, push it to the stack
 - If it is a closing symbol
 - If the stack is empty: return **FALSE**
 - Otherwise, pop from the stack. If the symbol popped does not match the closing symbol, return **FALSE**
- **Step 3:** At the end, if the stack is not empty, return **FALSE** (unbalanced), else return **TRUE** (balanced)

A running example

- ▶ Given an input symbol list: ({ [] }),
 - ▶ check if the symbols are balanced: show the status of the stack after each symbol checking

({ [] })

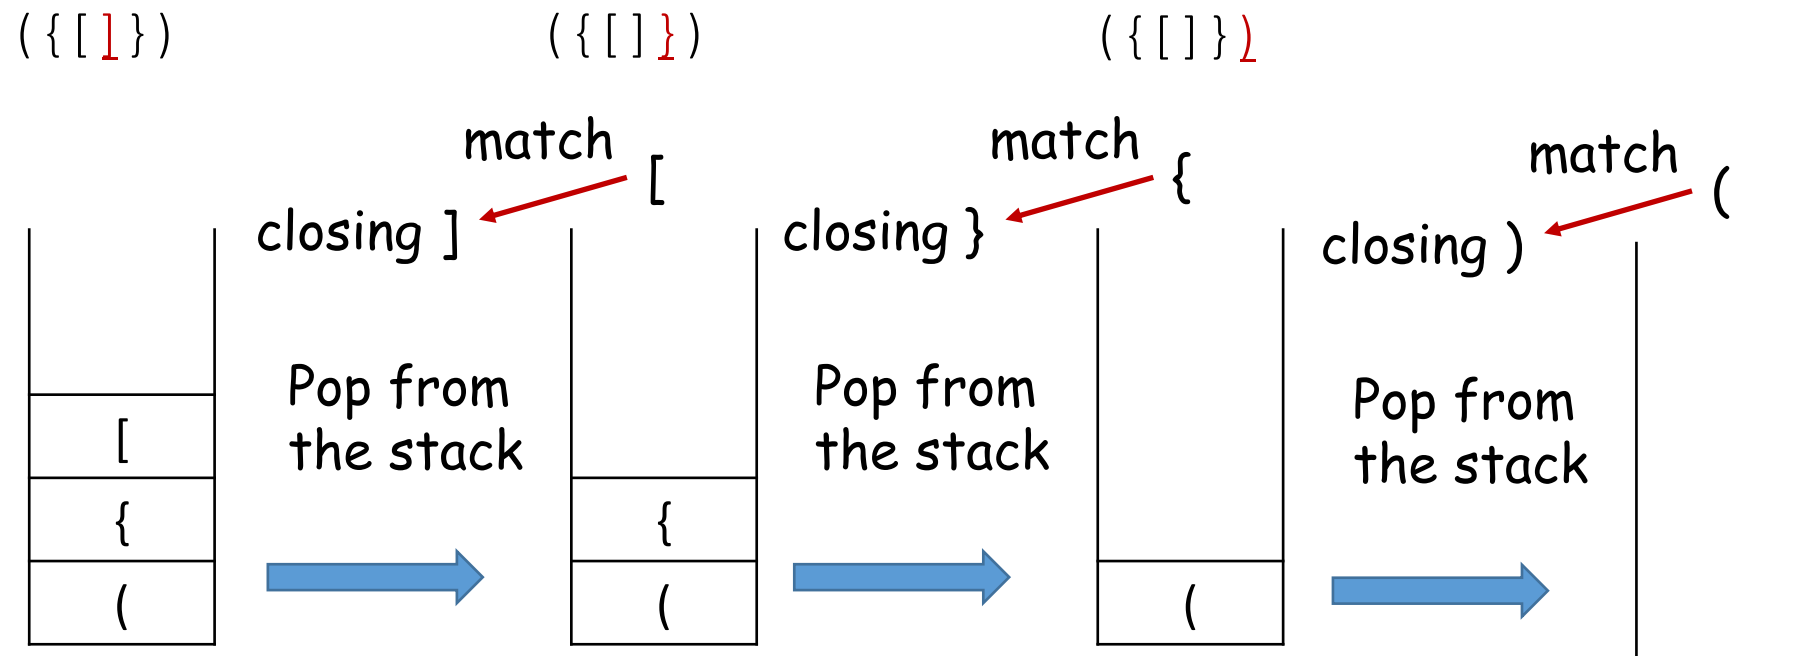

({ [] })

({ [] })

A running example

- ▶ Given an input symbol list: (`{[]}`),
 - ▶ check if the symbols are balanced: Show the status of the stack after each symbol checking

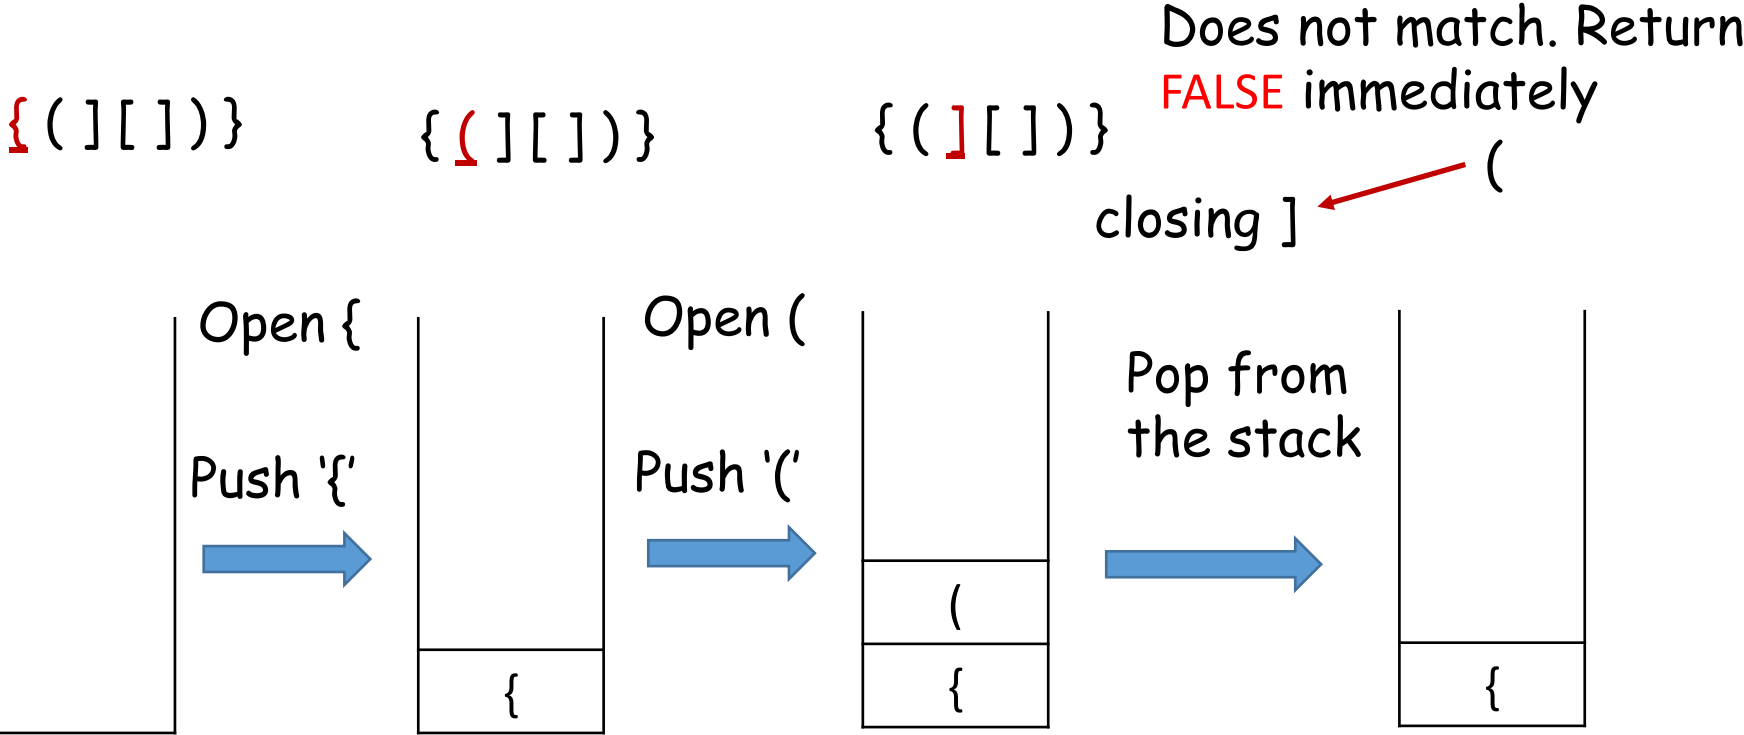

- ▶ After checking all symbols, the stack is empty: return **TRUE**

Practice

- Given an input symbol list: { (] []) },
 - Check if the symbols are balanced
 - Show the status of the stack after each symbol checking
- Given an input symbol list: () [[] { },
 - Check if the symbols are balanced
 - Show the status of the stack after each symbol checking

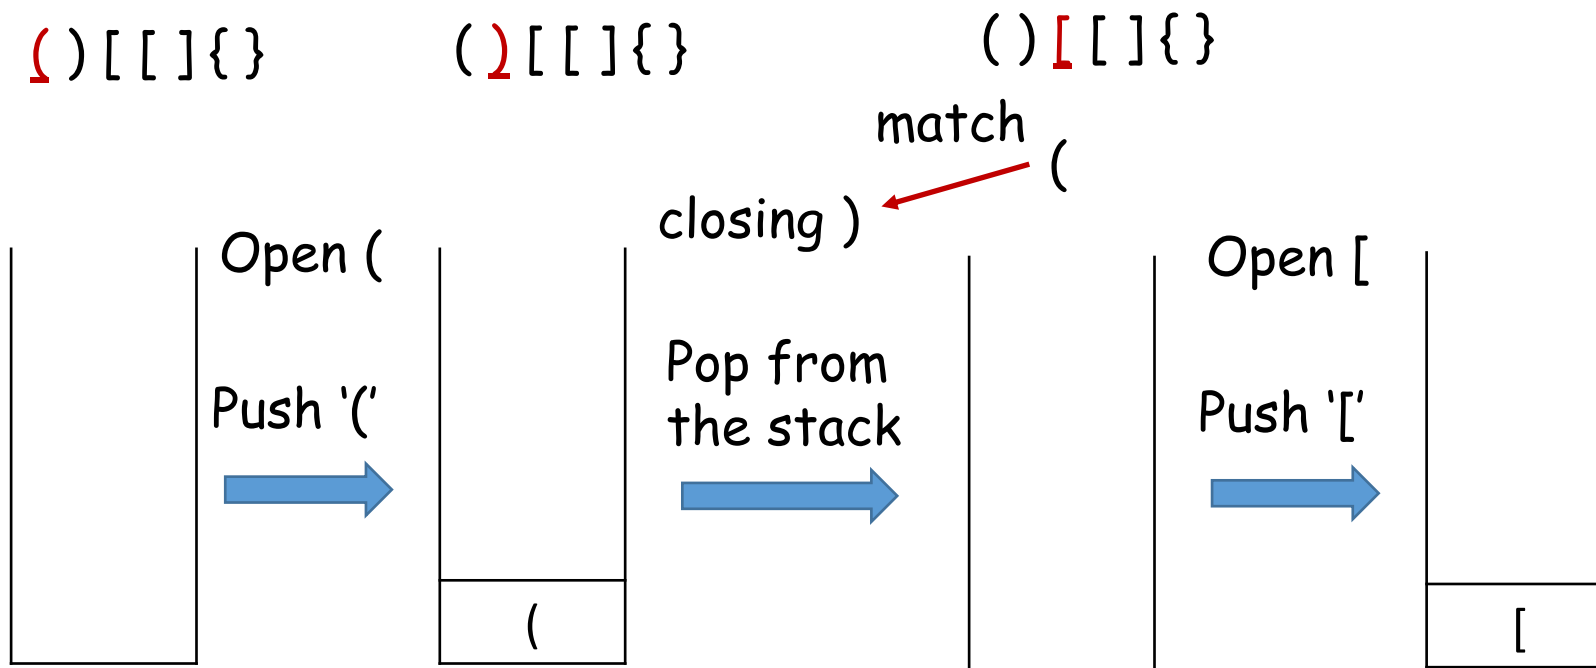

Practice

- Check if the symbol list { (] []) } is balanced
 - Show the status of the stack after each symbol checking

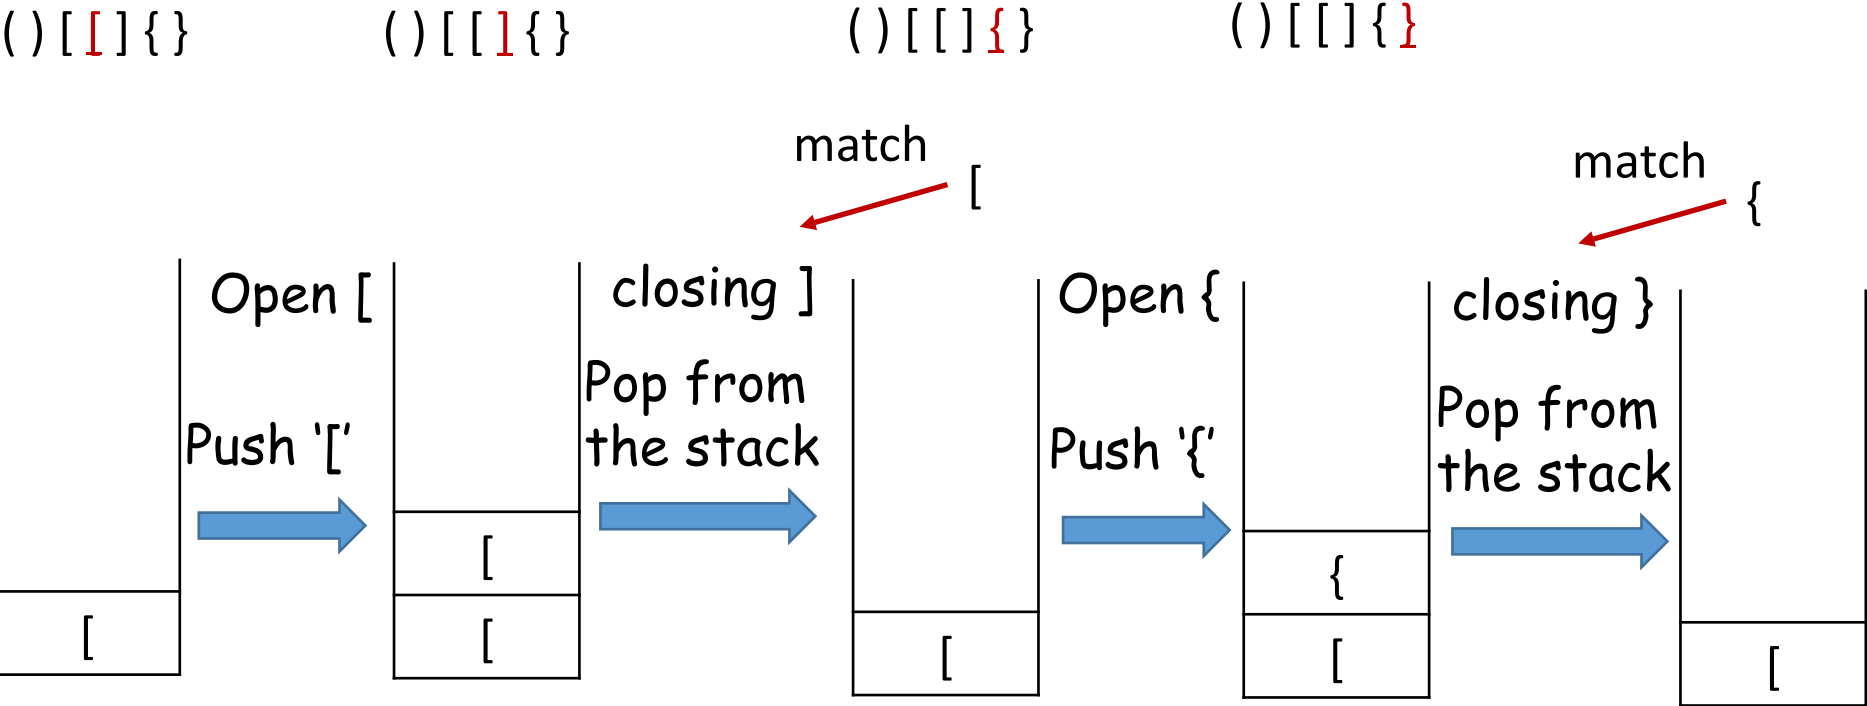

Practice

- Check if the symbol list () [[] { } is balanced
 - Show the status of the stack after each symbol checking

Practice

- Check if the symbol list () [[] { } is balanced
 - Show the status of the stack after each symbol checking

- Finally, the stack is not empty, so return **FALSE**

Solution:

```
from stack import ListStack

def is_matched(expr):
    lefty = '([{'
    righty = ')]}'

    s = ListStack()

    for c in expr:
        if c in lefty:
            s.push(c)
        elif c in righty:
            if s.is_empty():
                return False
            if righty.index(c) != lefty.index(s.pop()):
                return False
    return s.is_empty()

def main():
    expr = '1+2*(3+4)-[5-6]'
    print(is_matched(expr))
    expr = '(()))}]'
    print(is_matched(expr))
```

Practice: Matching Tags in HTML Language

- HTML is the standard format for hyperlinked documents on the Internet
- In an HTML document, portions of text are delimited by HTML tags. A simple opening HTML tag has the form “<name>” and the corresponding closing tag has the form “</name>”

HTML Tags

- Commonly used HTML tags that are used in this example include
 - `body`: document body
 - `h1`: section header
 - `center`: center justify
 - `p`: paragraph
 - `ol`: numbered (ordered) list
 - `li`: list item

An example of HTML document

```
<body>
<center>
<h1> The Little Boat </h1>
</center>
<p> The storm tossed the little
boat like a cheap sneaker in an
old washing machine. The three
drunken fishermen were used to
such treatment, of course, but
not the tree salesman, who even as
a stowaway now felt that he
had overpaid for the voyage. </p>
<ol>
<li> Will the salesman die? </li>
<li> What color is the boat? </li>
<li> And what about Naomi? </li>
</ol>
</body>
```

(a)

The Little Boat

The storm tossed the little boat like a cheap sneaker in an old washing machine. The three drunken fishermen were used to such treatment, of course, but not the tree salesman, who even as a stowaway now felt that he had overpaid for the voyage.

1. Will the salesman die?
2. What color is the boat?
3. And what about Naomi?

(b)

Solution:

Recall: find() method for a string in **Lecture 4**

Example

```
>>> data = 'From stephen.marquard@uct.ac.za Sat Jan 5 09:14:16 2016'  
>>> atpos = data.find('@')  
>>> print(atpos)  
21  
>>> sppos = data.find(' ', atpos)  
>>> print(sppos)  
31  
>>> host = data[atpos+1:sppos]  
>>> print(host)  
uct.ac.za
```

Solution:

```
from stack import ListStack

def is_matched_html(raw):
    s = ListStack()
    j = raw.find('<')

    while j != -1:
        k = raw.find('>', j+1)
        if k == -1:
            return False
        tag = raw[j+1:k]

        if not tag.startswith('/'):
            s.push(tag)
        else:
            if s.is_empty():
                return False
            if tag[1:] != s.pop():
                return False
            j = raw.find('<', k+1)

    return s.is_empty()

def main():
    fhand = open('sampleHTML.txt', 'r')
    raw = fhand.read()
    print(raw)
    print(is_matched_html(raw))
```

smaller-than sign

greater-than sign

opening tag

closing tag

Queue

- **Queue** is another fundamental data structure
- A queue is a collection of objects that are inserted and removed according to the **first-in, first-out (FIFO)** principle
- Elements can be inserted **at any time**, but only the element that has been in the queue **the longest** can be next removed

Applications of Queue

(a)

(b)

A long queue for covid19 test

The queue class

- The queue class may contain the following methods:

Q.enqueue(e): Add element *e* to the back of queue *Q*.

Q.dequeue(): Remove and return the first element from queue *Q*;
an error occurs if the queue is empty.

Q.first(): Return a reference to the element at the front of queue *Q*,
without removing it; an error occurs if the queue is empty.

Q.is_empty(): Return True if queue *Q* does not contain any elements.

len(Q): Return the number of elements in queue *Q*; in Python,
we implement this with the special method `__len__`.

The code of queue class

```
class ListQueue:
    default_capacity = 5

    def __init__(self):
        self.__data = [None]*ListQueue.default_capacity
        self.__size = 0
        self.__front = 0
        self.__end = 0

    def __len__(self):
        return self.__size

    def is_empty(self):
        return self.__size ==0

    def first(self):
        if self.is_empty():
            print('Queue is empty.')
        else:
            return self.__data[self.__front]
```

```
    def dequeue(self):

        if self.is_empty():
            print('Queue is empty.')
            return None

        answer = self.__data[self.__front]
        self.__data[self.__front] = None
        self.__front = (self.__front+1) \
            % ListQueue.default_capacity

        self.__size -=1
        return answer

    def enqueue(self, e):
        if self.__size == ListQueue.default_capacity:
            print('The queue is full.')
            return None

        self.__data[self.__end] = e
        self.__end = (self.__end+1) \
            % ListQueue.default_capacity
        self.__size += 1

    def outputQ(self):
        print(self.__data)
```

Practice: Simulating a web service

- An online video website handles service requests in the following way:
 - 1) It maintains a service queue which stores all the unprocessed service requests.
 - 2) When a new service request arrives, it will be saved at the end of the service queue.
 - 3) The server of the website will process each service request on a “first-come-first-serve” basis.
- Write a program to simulate this process. The processing time of each service request should be randomly generated.

Solution

```
from ListQueue import ListQueue
from random import random
from math import floor

class WebService():
    default_capacity = 5
    def __init__(self):
        self.nameQ = ListQueue()
        self.timeQ = ListQueue()

    def taskArrive(self, taskName, taskTime):
        if self.nameQ.__len__() < WebService.default_capacity:
            self.nameQ.enqueue(taskName)
            self.timeQ.enqueue(taskTime)
            print('A new task 《'+taskName+'》 has arrived and is waiting for processing...')
        else:
            print('The service queue of our website is full, the new task is dropped.')

    def taskProcess(self):
        if (self.nameQ.is_empty() == False):
            taskName = self.nameQ.dequeue()
            taskTime = self.timeQ.dequeue()
            print('Task 《'+taskName+'》 has been processed, it costs '+str(taskTime)+' seconds.')
```

Solution

```
def main():
    ws = Webservice()
    taskNameList = ['Dark knight', 'X-man', 'Kungfu', 'Shaolin Soccer', 'Matrix', 'Walking in the clouds' \
                    , 'Casino Royale', 'Bourne Supremacy', 'Inception', 'The Shawshank Redemption']

    print('Simulation starts...')
    print('-----')
    for i in range(1, 31):
        rNum = random()
        if rNum<=0.6:
            taskIndex = floor(random()*10)
            taskTime = floor(random()*1000)/100
            ws.taskArrive(taskNameList[taskIndex], taskTime)
        else:
            ws.taskProcess()
    print('-----')
    print('Simulation finished.')
```

Stack vs. Queue

- **Stack**

- The insertion and deletion operation can be performed from one side
- The stack follows the LIFO rule in which both the insertion and deletion can be performed only from one end

- **Queue**

- The insertion can be performed on one end, and the deletion can be done on another end
- The queue follows the FIFO rule in which the element is inserted on one end and deleted from another end

Practice: Simulating a stack using double queues

How to use double queues to implement a stack?

- idea?
- implementation?

Solution

```
from collections import deque
```

```
class StackUsingQueuesAlt:
```

```
    def __init__(self):  
        self.q1 = deque()  
        self.q2 = deque()
```

```
    def push(self, x):  
        self.q1.append(x)  
        print(f"Pushed {x} onto q1: {list(self.q1)}")
```

```
    def pop(self):  
        if self.is_empty():  
            print("Stack is empty.")  
            return None  
  
        # Move elements except the last one to q2  
        while len(self.q1) > 1:  
            item = self.q1.popleft()  
            self.q2.append(item)  
            print(f"Moved {item} from q1 to q2: {list(self.q2)}")
```

```
        # The last element in q1 is the top of the stack  
        popped_item = self.q1.popleft()  
        print(f"Popped {popped_item} from q1")
```

```
        # Swap q1 and q2  
        self.q1, self.q2 = self.q2, self.q1  
        print(f"Swapped queues. New q1: {list(self.q1)}")  
        return popped_item
```

```
    def top(self):  
        if self.is_empty():  
            print("Stack is empty.")  
            return None  
  
        while len(self.q1) > 1:  
            self.q2.append(self.q1.popleft())
```

```
        # Get the last element  
        top_item = self.q1[0]  
        self.q2.append(self.q1.popleft())  
        print(f"Top element is {top_item}")
```

```
        # Swap q1 and q2  
        self.q1, self.q2 = self.q2, self.q1  
        return top_item
```

```
    def is_empty(self):  
        return not self.q1
```
